Dear Danny: Your sentence in Sec 5 means this to me:

"In a previous attempt to fit Φ beyond 2 MeV we encountered that our minimization could not find steps in the best fit above this energy. This is a problem we encountered many times before at all energies, and we found it was due to numerical issues that we corrected which lead to finding except at high energies. But this time instead of putting in the time to understand why our minimization failed above 2 MeV, we decided to cut this energy region off and come up with the BOGUS explanation in this section to explain it. The problem above 2 MeV may also have been because we were double counting h_i but we do not bother to explain what we actually did. "

This sentence does not make sense....If what you say is true, why did we write the paper?

With respect to what you added later, when explaining why the bias and dispersion close to 2 MeV are large, your sentence ADDS NOTHING to the explanation within the method we used, which fit up to 2 MeV only. So why mention what happened in a different method, different χ^2 in which it made sense to go to energies higher than 2 MeV?

BUT CONFUSES THINGS A LOT: Are you saying your method does not work beyond 2 MeV? Why does it not work beyond? Why is the failure not clearly explained in the paper? Since $\Delta\Phi$ is defined only below 2 MeV what were you trying to fit before above this energy? Did you still use h_i as background which could lead to double counting?

An attentive referee will ask :

---add the clear explanation of what error of "non-stabilization" you wanted to avoid beyond 2 MeV?

---your $\Delta\Phi$ does not go beyond 2 MeV so how did you want to fit it above?

--- If it was a different model, with different choice of intervals, please explain clearly your method when you found this error of "non stabilization"

---Were you double counting when considering h_i as background (namely Φ known above 2 MeV) and simultaneously trying to fit it beyond? Or you were not taking h_i as background. What was the chisquare you were using in the other method where you were fitting beyond 2 MeV

Graciela

We can't rewrite history. There was a stabilization problem that we fixed by truncating the kernels. Ko, Muping, for the third time, can you confirm this?

Are you suggesting that we not mention this to avoid a referee's scrutiny? I don't accept that.
